Ski areas across the country are committed to lift safety and have an excellent safety record for uphill transportation as a result of this commitment. In fact, there is no other transportation system that is as safely operated, with so few injuries and fatalities, as the uphill transportation provided by chair lifts at ski resorts in the United States. The National Ski Areas Association (NSAA) compiles and updates this Ski Lift Safety Fact Sheet annually to provide ski areas and the public with the most current information on the ski resort industry’s commitment to overall lift safety, financial investment in lifts and lift maintenance, industry education and training on lifts, and frequently asked questions about ski lifts.

Ski Lift Safety in Context

Riding a chairlift or gondola while skiing, snowboarding, mountain biking, or even just sightseeing, is an exceptionally safe and secure mode of transportation. Deaths from malfunctions of ski lift operations in the United States have occurred rarely over the past several decades. Since 1973 (when NSAA began tracking skier visits and retaining related statistics), there have been 12 deaths attributed to ski lift malfunctions,1 a 41-year span during which the industry provided more than 15.9 billion lift rides to skiers and snowboarders.2 Notably, the ski resort industry in the United States has not experienced a fatality resulting from a lift malfunction since 1993, a 21-year period. To put this into context, in this 41-year

---

1 NSAA first began tracking skier visits during the 1978/79 season. Therefore, for the five seasons prior (1973/74 to 1977/78), NSAA uses a very conservative estimate of 39.7 million skier visits for each of these five seasons (which is the lowest season recorded during the 1980-81 season).

2 During this 41- season time period, U.S. resorts averaged 51.7 million skier/snowboarder visits per season. To derive the 15.9 billion lift rides during this period, we multiplied the average number of skier visits (51.7 million) during the 41-year span, resulting in a total of 2,119,700,000 skier visits. We conservatively assumed that each skier visit resulted in 7.5 ski lift rides per visit, and then multiplied 7.5 lift rides by 2.119 billion, resulting in 15,897,750,000 lift rides (15.9 billion).
span, the ski industry has transported guests more than 7.95 billion miles in lift rides – that’s more than 85 trips from the Earth to the Sun.³

Given the exceedingly rare number of fatalities involved due to ski lift malfunctions, and the billions of miles transporting guests, the industry’s fatality rate is extremely low. As of the 2013/14 ski season, which is the most current data available, the annual fatality rate per 100 million miles traveled on ski lifts was 0.138 – far safer, in comparison, than annual fatality rates of riding an elevator or in automobiles.⁴ See Table 1 below. In short, a passenger is five times more likely to suffer a fatality riding an elevator than riding a ski lift, and eight times more likely to suffer a fatality in a car than from a ski lift.

Table 1: FATALITY RATE COMPARISON*

According to the Bureau of Labor Statistics, there are on average ten passenger fatalities per year from riding elevators.⁵ With elevators transporting passengers 1.36 billion miles per

* NOTE: Because of limitations in the availability of statistics from various organizations, it is difficult to compare year to year statistics for chairlifts, elevators, and automobile fatalities. As a result, we use data from the most current year available for each. For example, while there is chairlift data from the 2013/14 season, the most currently available data for automobile fatalities is from 2012.

³ If one assumes each lift ride is one-half mile long in distance traveled, U.S. ski areas have transported skiers/snowboarders 7.95 billion miles during the past 41 ski seasons (15.9 billion lift rides multiplied by 0.5 miles traveled = 7.95 billion miles traveled on lifts. The distance from the Earth to the Sun is 93 million miles.

⁴ U.S. ski areas had 56.54 million skier visits in the 2013/14 season. This number is multiplied by 7.5 ski lift rides per visit, with an average ride distance of 0.5 miles, resulting in 212,025,000 passenger miles during the 2013/14 ski season. With a total of 12 fatalities resulting from chairlift malfunctions over 41 years, the fatality rate in that span is 0.293 fatalities per year. The fatality rate per year, divided by passenger miles, equates to 0.138 fatalities per 100 million miles of passengers transported by ski lifts.

⁵ According to the U.S. Bureau of Labor Statistics (BLS), Census of Fatal Occupational Injuries, 1992-2009 data, there were, on average, 5 fatalities among passengers while using elevators at work (for proper comparison, this statistic only includes passenger fatalities, and excludes fatalities involving employees working on or around
year, there is an average passenger fatality rate riding elevators of 0.735 per year (per 100 million miles traveled).

“In short, a passenger is five times more likely to suffer a fatality riding an elevator than a ski lift, and more than eight times more likely to suffer a fatality riding in a car than on a ski lift.”

In fact, driving an automobile is far more dangerous than riding ski lifts. In 2012, 36,300 people died in motor vehicle accidents in the United States, for a death rate of 1.23 for every 100 million-vehicle miles. The fatality rate per automobiles is more than eight times the 0.138 fatality rate for transport on a ski lift.

The most recent death of a guest due a lift malfunction at a U.S. ski resort was in 1993, when a Sierra Ski Ranch detachable-grip lift failed. In 1985, there were two deaths caused by a malfunction of a lift at Keystone ski area in Colorado. There have been no other deaths related to lift malfunctions in the 1980s or 1990s at U.S. ski resorts.

Fatalities from lift-related malfunctions in the U.S. are a fraction of the number of fatalities at European ski resorts due to lift malfunctions. While there have been 12 lift-related fatalities at American ski areas since 1973, over that same time frame, there have been at least 102 fatalities at European resorts from lift malfunctions — nine times the fatality rate of American ski areas.

---

8 Two other deaths were attributed to chairlifts that occurred during non-operating hours, and one fatality that was not attributed to any lift malfunction. One fatality was an industrial accident at Copper Mountain, Colo., in August 1975 that involved an employee conducting summer maintenance (for statistical comparison purposes, only fatalities for passengers, not employees, are counted). The other fatality was at the Seattle Mountaineering Club, Washington, in 1997, when a child was tangled in a surface rope tow during non-operating hours at a private ski club that was not open to the public. Lastly, in 2009 at Heavenly Mountain Resort, CA, there was a fatality when a guest fell from a chairlift as a result of an entanglement from a broken zip line retrieval chord; this death was not attributable to any chair lift malfunction.

9 See Reuters, Sept. 6, 2005, “Chronology—Major Accidents in Ski Resorts”
To be sure, ski areas are not immune from lift-related malfunctions which cause injuries and fatalities, but they are quite rare. Below is the history of ski lift-related malfunctions in the United States that resulted in fatalities, listed below chronologically:

Falls From Chairlifts

It is extraordinarily rare for a fatality to occur as the result of a fall from a chairlift which is not attributed to a mechanical malfunction or operation of the chairlift. On December 18, 2011, a seven-year old boy died after falling from a chairlift at Sugar Bowl, Calif., the only known fatality of a minor that has occurred in the industry as a result of falling from a chairlift. An investigation of the incident conducted by the Placer County Sheriff’s Department found the cause of the incident to be inconclusive, but the cause was not attributed to mechanical or technical error. On February 25, 2004, a skier died when he fell from a chairlift at Snow Trails ski area in Ohio, and it was unclear whether he died from a medical condition, or as the result of the fall.

Passengers falling out of chairlifts are typically not recorded or collected by most state regulatory agencies. The best statistical information regarding the causes of falls from ski chairlifts comes from the state of Colorado. With 29 ski areas – ranging in overall size, terrain, vertical steepness, lift capacity, age, and variety of chairlifts, the state accounts for nearly one-fifth of all skier visits in the country – Colorado is clearly representative for the broader ski industry. Unlike most states, Colorado law requires ski areas to report any falls from chairlifts resulting in injury, and the cause of the fall, to the Colorado Passenger Tramway Board, a state regulatory agency that oversees chairlift safety and operation.

Through the state’s freedom of information law, NSAA obtained data from the Colorado Passenger Tramway Board in order to analyze and interpret the reason and frequency of falls from chairlifts, in an effort to better understand the safety considerations for the operation of chairlifts. Accordingly, NSAA analyzed Colorado data from the 2001/02 to 2011/12 ski seasons. In that 11-season period, ski areas reported 227 falls from chairlifts to the Colorado Tramway Board, and the causes reported for the falls (human error, medical condition, operator/mechanical error, or unknown cause). (See Graph 1 below).
The results of this analysis establish that 86 percent of all falls are attributed to skier error and four percent of falls are due to medical issues of the rider. Notably, only 2 percent of all falls from chairlifts were the result of mechanical or operator error, reinforcing the overall safety of chairlift operations. (See Graph 2 below).
Also, 71 percent of all falls from lifts occurred on chairlifts which had a restraint bar. (See Graph 3 below).

GRAPH 3

In 2002, the *Denver Post* studied years of data collected by Colorado’s Tramway Safety Board regarding falls from chairlifts in Colorado. According to the *Denver Post*, “[a]n analysis of state accident reports by the *Denver Post* shows that human error – rather than mechanical problems, unsafe operation or weather conditions – is the cause of most falls from ski lifts.”

As the *Denver Post* explained in their review of the agency’s data, “[m]ost falls happen because of mistakes getting on, when skiers sit down badly or shift their weight too fast, or getting off, when skiers move forward too soon and lose their balance on the seat.”

In addition to the safe operation of chairlifts by ski resorts, skiers and snowboarders have a corresponding obligation to ride and use chairlifts in safe and responsible manner. According to the ski industry’s “Your Responsibility Code” – the seven-point ethics code adopted by the ski industry and NSAA in 1965 which has been adopted in skier safety legislation

---

10 See “Falls from Lift a Skiing Risk, but Serious Accidents Rare,” *Denver Post*, Dec. 8, 2002.
in many states – skiers and snowboarders are personally responsible to “know how to use the lifts safely.”

On rare occasion, an individual may fall from a chairlift that is neither the result of mechanical malfunction nor human error, but can be attributed to a pre-existing medical condition of the skier or rider. For example, an individual may suffer a heart attack, stroke, seizure, or other medical event while riding a chairlift, which causes the person to fall. When this results in a fatality to the rider, it is often undetermined as to the actual cause of the fatality (the medical condition itself, the fall, or some combination). Because these fatalities do not reflect the overall safety of riding chairlifts for the public, understandably, these rare incidents are not included in industry fatality data.

**Lift Inspections and State and Federal Regulation**

Ski areas adhere to rigorous and exacting inspections procedures for the lifts at their resorts, and the fact that ski areas have not had a fatality due to a lift-related malfunction in 21 years is attributed to their meticulous inspection and maintenance programs. Ski area employees conduct their own individual inspection of theirs lifts on a daily, weekly, monthly, and annual basis. This year-round maintenance regimen is conducted pursuant to state agencies, lift manufacturer requirements, federal requirements, national safety standards and other inspection entities.

The American National Standards Institute (“ANSI”) – a national, non-profit umbrella accrediting organization which oversees standard-setting committees for nearly every industry in the United States – has a standards committee dedicated solely to ski lifts and passenger ropeway systems. Safety standards for ski lifts have been established by the ANSI Accredited Standards Committee B77 (“B77” for short), which was started back in 1956 to recommend safeguards, principles, specifications, and performance objectives that would reflect the current state of the art of passenger ropeway design, operations, and maintenance. This B77 Committee – which sets national consensus safety standards – is comprised of government regulators, engineers, lift manufacturers, ski area owners and operators, academics, and other members of the public interested in ski lift design, operation, and maintenance. Membership on the B77 Committee is open to the public. The B77 Committee meets several times each year to address concerns by Committee members, review new technology, analyze incidents involving lifts and ropeways, and vote on updates and changes to these safety standards on a regular basis. The current standards regulating ski lifts were most recently approved in 2011.

In turn, state regulatory agencies have adopted these B77 safety standards (and codified them into law) to govern ski lifts and passenger ropeway transportation. In addition to these B77 standards, ski areas are subject to inspection by regulators from state agencies governing

---

11 Canada has a parallel standards committee, known as the Z98 standards, which are similar to ANSI B77 standards in the United States.
ski lifts based on the B77 standards. Furthermore, most states and other inspection entities require impartial, third-party engineers to conduct lift inspections. In fact, most states require surprise, unannounced chair lift inspections during the course of the ski season as part of the regulatory framework for lift safety.

Additionally, ski areas operating on National Forest System lands must adhere to lift-related requirements in their special use permits. The U.S. Forest Service requires certification and inspection of lifts in accordance with the ANSI B77 Committee standards. The U.S. Forest Service is a member of the ANSI B77 Committee and monitors ski lift construction and operation on public land.

As part of ski areas’ maintenance and inspection procedures, independent specialists are brought in to inspect the wire ropes (the cable that carries the chairs) and chairlift grip testing. Areas routinely inspect tower footings that support the lift equipment, the sheaves that support the haul rope on the towers, gear boxes, brakes, and the electric motors powering the lifts, as well as other components. In fact, all ski lifts are required to have auxiliary engines as back-up power sources, in case there is a loss of electrical power. Lastly, ski areas routinely practice chair lift evacuation drills with their ski patrols in case of hazardous conditions or lift malfunctions.

**Ski Resorts Invest Heavily in New and Upgraded Lifts**

Ski areas across the country invest heavily in new and upgraded lifts. During the 2013/14 season, ski areas spent $60 million on new and upgraded lifts (compared to $44 million in 2012/13), according to the 2013/14 NSAA Kottke End of Season Survey. For the upcoming 2014/15 season, lift manufacturers indicated that they expected to install more than 35 new or upgraded chair lifts, with capital expenditures for the 2014/15 season estimated at more than $55 million. Capital expenditures on new and upgraded lifts are well over $1 billion going back to the 1996/97 ski season.

**Technical Training and Education**

The ski industry has a long-standing and exhaustive training and educational regimen for ski lift operators across the United States. The Rocky Mountain Lift Association (RMLA) is a trade association for maintenance and operation personnel for ski lifts and ropeways. Going back to 1970, RMLA has hosted an annual educational conference since 1970 in the western United States, with more than 375 attendees from ski areas participating in more than 70 different educational presentations and seminars on issues relating to lift safety, maintenance, and lift operations. Similarly, for ski areas located in the eastern U.S., the annual Lift Maintenance Seminar (LMS) has been holding similar educational workshops each year, going back to 1976.

In addition to these two mainstays of lift training and maintenance, there are numerous other regional workshops on lift maintenance, lift safety, and lift operations. There are lift
maintenance seminars conducted annually by the Midwest Ski Areas Association, the Pacific Northwest Ski Areas Association, the Ski Areas of New York, and the Intermountain Ski Areas Association, and the New England Ski and Sports Summit. Indeed, the National Ski Areas Associations features lift operations seminars at their two annual winter conferences, in addition to nine regional locations during the NSAA Fall Risk Management pre-season workshops conducted annually. Lastly, the two main lift manufacturers in the United States – Doppelmayr USA and Leitner-Poma – conduct their own training and educational seminars for ski areas which have installed their lifts.

The comprehensive and exhaustive extent on training and educational opportunities for lift maintenance and safety in the industry is a testament to the amazing level of guest safety at ski areas across the United States.

Frequently Asked Questions

Q: How many ski lifts are there in U.S.?

A: Approximately 3,500 – the vast majority which are traditional double, triple, and quad chair lifts (both fixed and detachable), as well as gondolas, surface lifts, rope tows, and aerial tramways.

Q: What is the average age of lifts installed in the U.S.?

A: It is difficult to accurately establish the average age of chair lifts, particularly in light of the fact that the vast majority of lifts have received significant upgrades to their dynamic machinery and critical components since installation. However, a clear majority of lifts were installed after 1980, and survey data indicates that 83 percent of all fixed grip lifts have been installed since 1970. Less than 1 percent of fixed grip chairs lifts were installed prior to 1960. Regardless of the date of initial installation, lifts can operate safely with proper maintenance and inspection for several decades. Rapid growth and investment in the ski resort industry occurred in the 1970s, 80s, and 90s, and well into the first decade of the 21st century, when the vast majority of chair lifts, gondolas, and other uphill transports were installed.
Q: **Do manufacturers or state regulators have a recommended lifespan for ski lifts?**

A: There is no recognized or consensus recommended lifespan for a ski lift, either based on the manufacturers’ perspective or state regulators. Moreover, the ANSI B77 Committee does not consider or evaluate the overall safety of a lift based on its date of installation. Lifts are continually maintained and inspected on a daily, weekly, monthly, and annual basis, and moving parts (such as haul rope, sheaves, controls, drive systems, motors, gear boxes, bearings, and other components) are frequently being replaced or upgraded during the life of the lift. In addition, some chair lifts are operated at varying degrees of capacities (some lifts operated at full capacity all the time, some lifts are frequently idled, some lifts are operated both winter and summer seasons, etc). **Simply put, the date of initial installation of a lift is not indicative of the lift’s overall level of safety.** Indeed, the last two lift malfunctions which resulted in fatalities (one incident in 1993, the other in 1985) both occurred on lifts that were less than one year old. Well maintained ski lifts – with proper maintenance and equipment upgrades – can operate effectively for decades past their date of original installation.

Like automobiles, a person would not replace a car simply because it needed new tires; likewise, a ski area would not replace an entire lift system (many which are a half-mile in length or longer) when upgrading components will allow the lift system to continue to operate safely and effectively.

Q: **How do resorts determine when to discontinue lift operations due to weather conditions?**

A: It’s a case-by-case basis, and there is no one-size-fits all procedure or protocol used in the industry. Usually, the decision to shut down a lift is determined by a select group of ski area managers, which may include the general manager, ski patrol director, the risk manager, and/or the manager of the lifts department. Moreover, different considerations would be used for different lifts at the same resort; some lifts located at higher elevations may be more exposed to wind and other conditions than lifts closer to the base of the resort. It is not unusual for a ski area to close a lift due to weather conditions.

Q: **Do some states require restraint bars on chairlifts?**

A: Most states do not require chair lifts to have restraint bars installed. All seven of the states in the Northeast (Connecticut, Maine, Massachusetts, New Hampshire, New York, Vermont, and Rhode Island) require that chairlifts have a restrain bar installed. Vermont is the only state that requires that chairlift users ride the lift with the restraint bar lowered while in operation. While most states do not require restraint bars, both major manufacturers of chairlifts in the United States offer restraint bars as standard equipment.
Additional Media Resources on Ski Lift Safety and Operation

Jim Fletcher, P.E., Professional Engineer and senior consultant with Engineering Specialties Group, a professional engineering firm; member on the ANSI B77 Standards Committee; for the past several decades, Jim Fletcher has worked as an engineer on numerous transportation projects around the country, including projects in the ski industry, as an independent, outside consultant. He is not associated or employed with any ski areas.
